DEEP LEARNING AND COMPUTER VISION

Mecha tronics

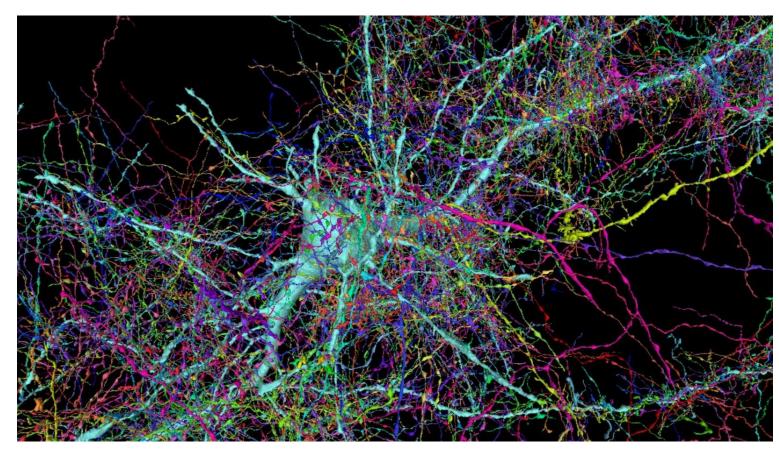

Day9 Deep Learning

AI ML and DL

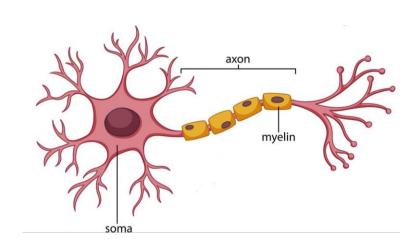

- Deep Learning is a specialized field of Machine Learning that relies on training of Deep Artificial Neural Networks (ANNs) using large dataset such as images.
- ANNs are information processing models inspired by the human brain.

Artificial Neural Networks (ANNs)

Human Neural Networks

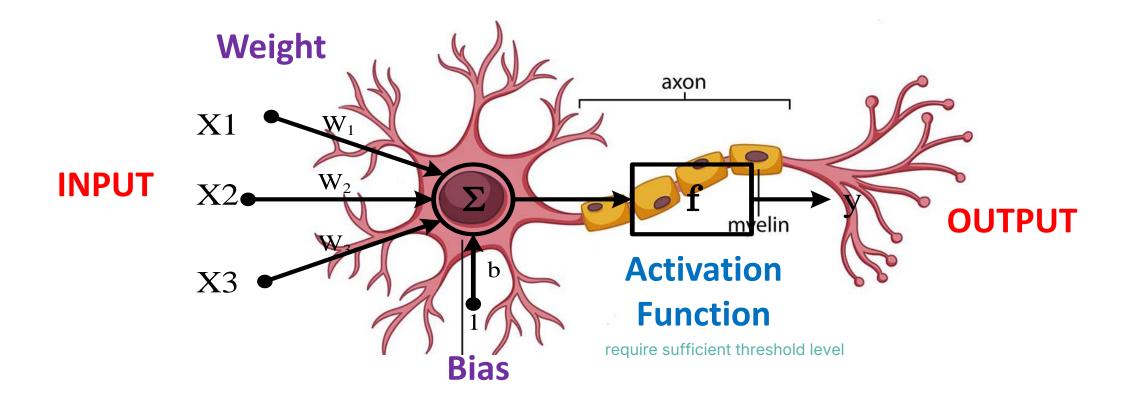

Neuron

Artificial Neural Networks (ANNs)

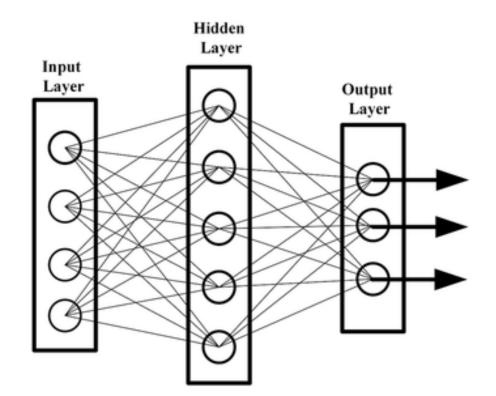

Artificial Neural Networks (ANNs)

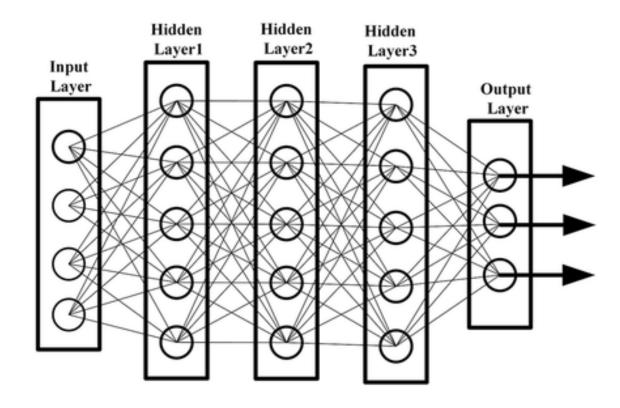

Deep Neural Networks

start from 3 perceptrons

Artificial Neural Network

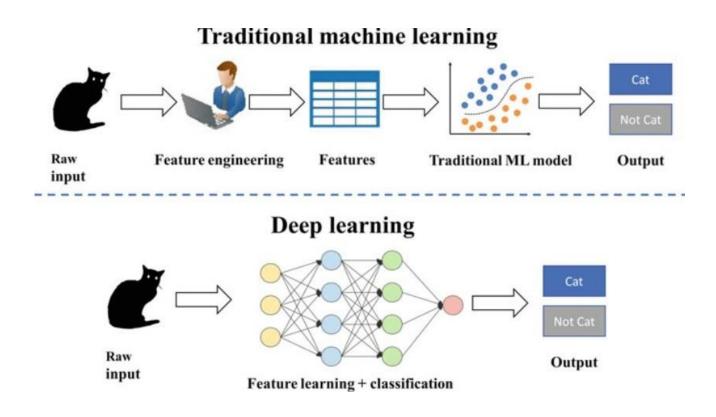

Deep Neural Network

Machine Learning vs Deep Learning

- Machine learning Process: (1) select the model to train, (2) manually perform feature extraction.
- Deep Learning Process: (1) Select the architecture of the network,
 (2) features are automatically extracted by feeding in the training data along with the target class (label).

Human and Deep Learning Concept

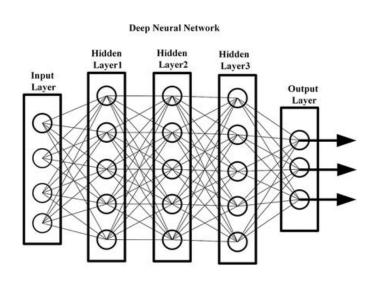

similar to labeling in supervised learning

Human and Deep Learning Concept

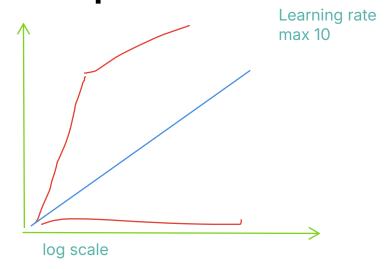

Smaller network → Smaller brain → Smaller capability

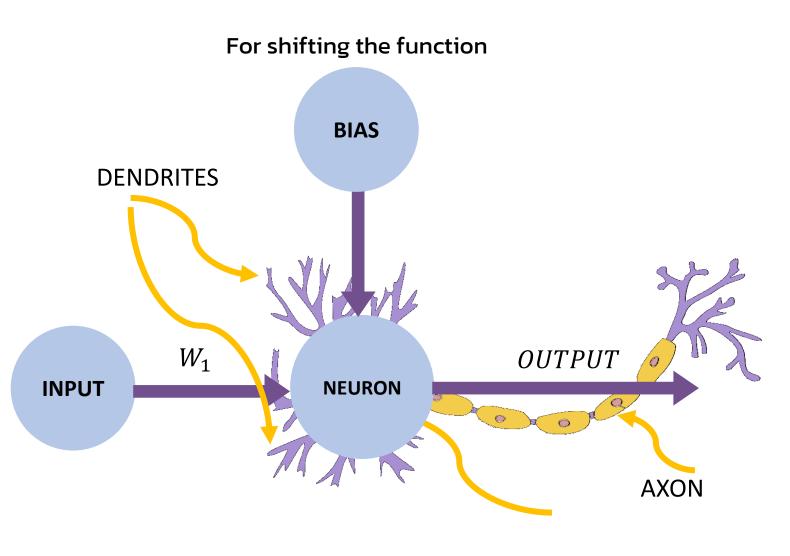

Simple Neuron

$$Output = \boxed{Input * W_1 + Bias}$$

Model Parameter

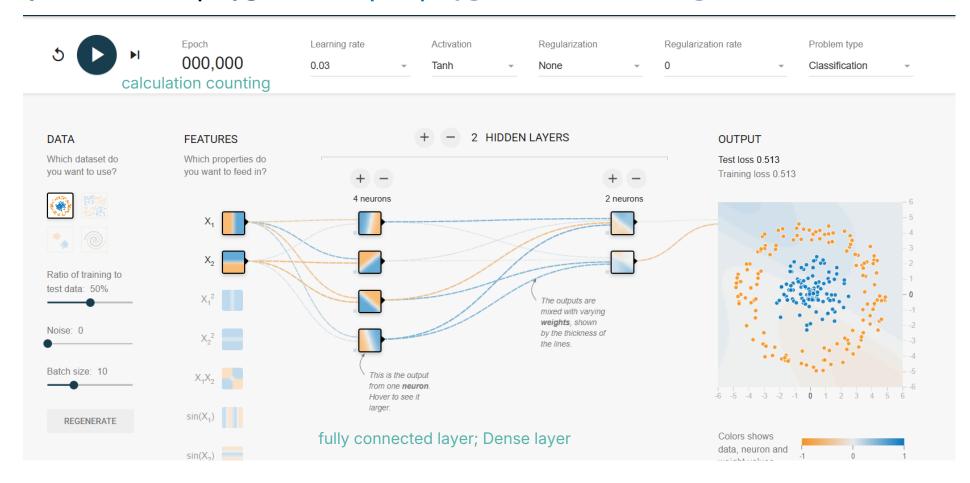

⇒Learning parameters that needs to tuning

10

TensorFlow Playground

Let's play at tensorflow playground: https://playground.tensorflow.org/

DL Development Tools

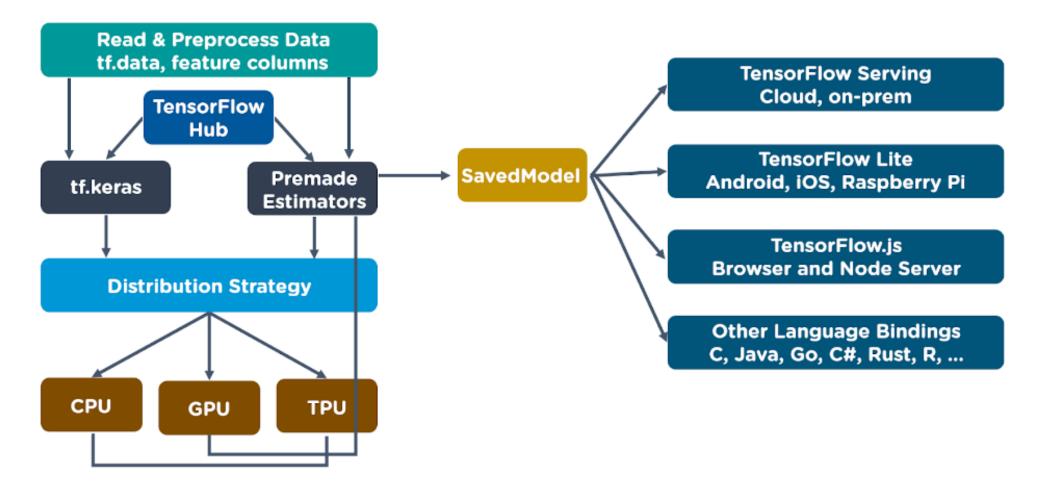

TensorFlow

TensorFlow Installation

CPU: pip install tensorflow

GPU: pip install tensorflow-gpu

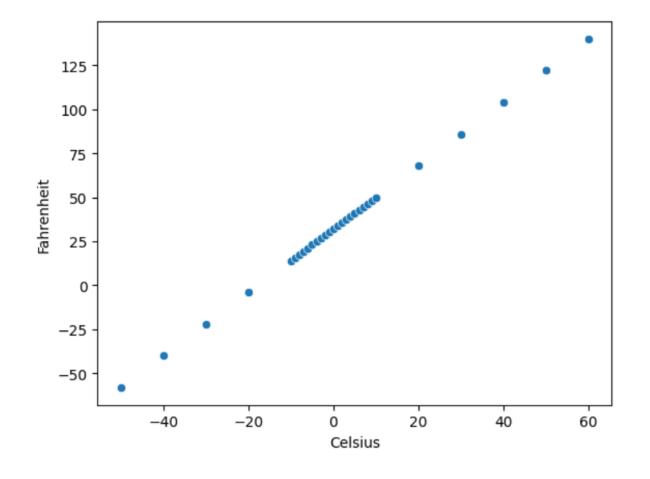

Install by specify the version

!pip install tensorflow-gpu==2.11.0

From the CSV data, create the model to predict the value of output from desired input using TF.

	Celsius	Fahrenheit
0	-50	-58.0
1	-40	-40.0
2	-30	-22.0
3	-20	-4.0
4	-10	14.0
5	-9	15.8
6	-8	17.6
7	-7	19.4

Step1: Import Library

```
import tensorflow as tf
import pandas as pd
import numpy as np
import seaborn as sns
import matplotlib.pyplot as plt
```

Step2: Read data from CSV

	Ceisius	rain ennert
0	-50	-58.0
1	-40	-40.0
2	-30	-22.0
3	-20	-4.0
4	-10	14.0
5	-9	15.8

Calsius Fahranhait

df = pd.read_csv("/content/drive/MyDrive/

ex1_simple_perceptron.csv")

Patiroi CSV File

Step3: Show statistical parameters.

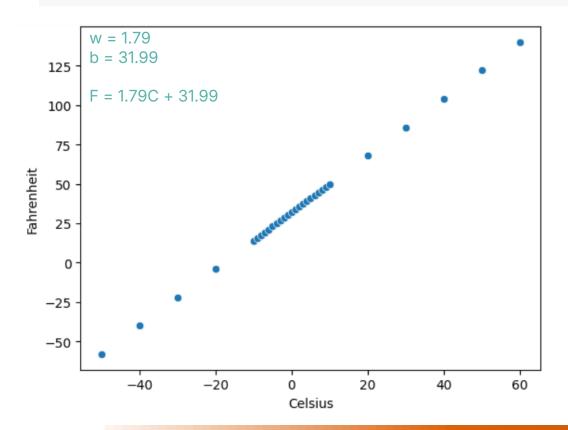

df.describe()			
	Celsius	Fahrenheit	
count	30.000000	30.000000	
mean	2.000000	35.600000	
std	22.780815	41.005466	
min	-50.000000	-58.000000	
25%	-6.750000	19.850000	
50%	0.500000	32.900000	
75%	7.750000	45.950000	
max	60.000000	140.000000	

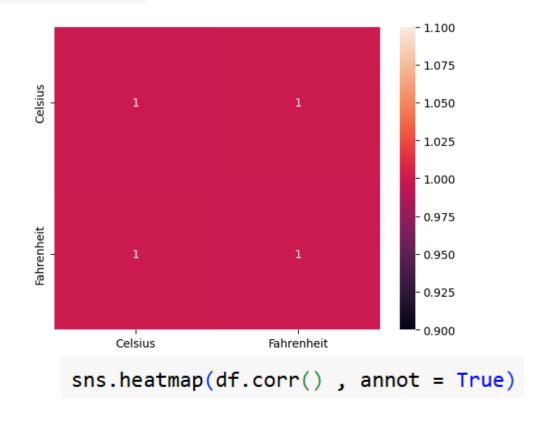

Step4: Get data information

```
df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 30 entries, 0 to 29
Data columns (total 2 columns):
    Column
               Non-Null Count Dtype
0 Celsius 30 non-null
                               int64
   Fahrenheit 30 non-null
                              float64
dtypes: float64(1), int64(1)
memory usage: 612.0 bytes
```

Step5: Visualize dataset.

```
sns.scatterplot(data = df , x = 'Celsius', y = 'Fahrenheit')
```

18

Step6: Create Datasets

```
x_train = df['Celsius']
y_train = df['Fahrenheit']
```

Step7: Create Model

Non-trainable params: 0 (0.00 B)

```
model = tf.keras.Sequential()
model.add(tf.keras.layers.Dense(1, input_shape=[1]))
model.summary()
```

Why it has 2 parameters?

Layer (type)	Output Shape		Param #
dense_4 (Dense)	(None, 1)		2
Total params: 2 (8.00 B) Trainable params: 2 (8.00 B)			

Step8: Train the model.

momentum; like ของจากพื้นเอียง

```
model.compile(optimizer=tf.keras.optimizers.Adam(0.5), loss='mean_squared_error')

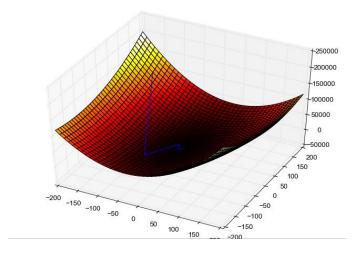

Adam = Adaptive Moment Estimation
Learning rate

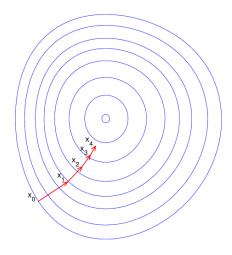

Loss Function
```

epochs_hist = model.fit(x_train, y_train, epochs = 300)

Gradient Descent

- Gradient descent is an optimization algorithm used to obtain the optimized network weight and bias values
- It works by iteratively trying to minimize the cost function
- It works by calculating the gradient of the cost function and moving in the negative direction until the local/global minimum is achieved
- If the positive of the gradient is taken, local/global maximum is achieved

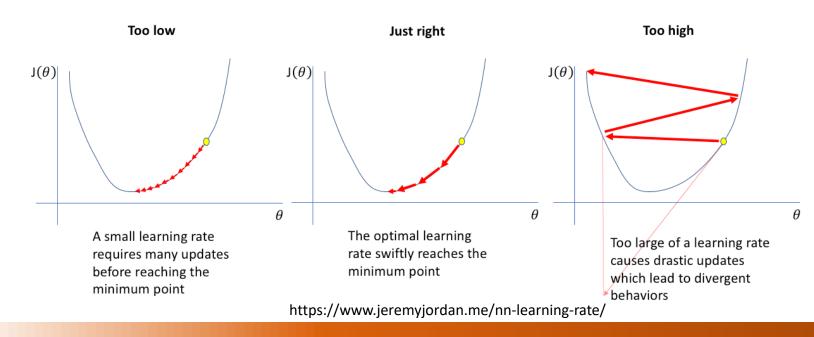

Learning Rate

- The size of the steps taken are called the learning rate
- If learning rate increases, the area covered in the search space will increase so we might reach global minimum faster
- However, we can overshoot the target
- For small learning rates, training will take much longer to reach optimized weight values

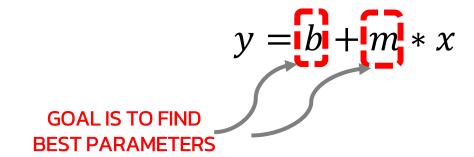

Gradient Descent

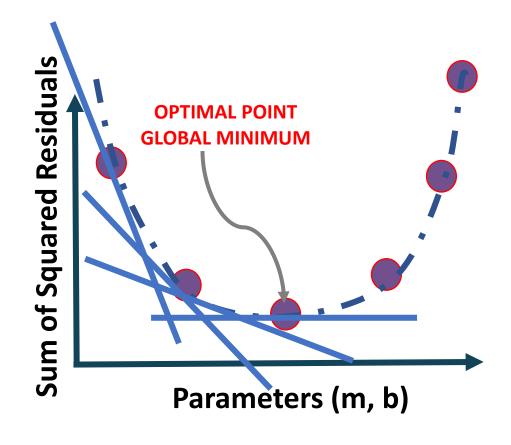

Gradient descent works as follows:

- 1. Calculate the derivative (gradient) of the Loss function
- 2. Pick random values for parameters m, b and substitute
- 3. Calculate the step size (how much are we going to update the parameters?)

4. Update the parameters and repeat

*Note: in reality, this graph is 3D and has three axes, one for m, b and sum of squared residuals

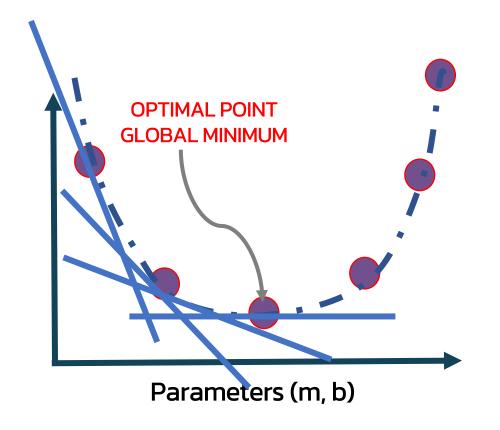

Gradient Descent

$$y = b + m * x$$
GOAL IS TO FIND
BEST PARAMETERS

Loss Function
$$f(m,b) = \frac{1}{N} \sum_{i=1}^{n} (y_i - (b+m*x_i))^2$$

gradient
$$f'(m,b) = \left[\frac{df}{dm} \frac{1}{N} \sum_{i=1}^{n} -2x_i (y_i - (b+m*x_i))^2 \frac{1}{N} \sum_{i=1}^{n} -2(y_i - (b+m*x_i))^2 \right]$$

*Note: in reality, this graph is 3D and has three axes, one for m, b and sum of squared residuals

Mean Square Error

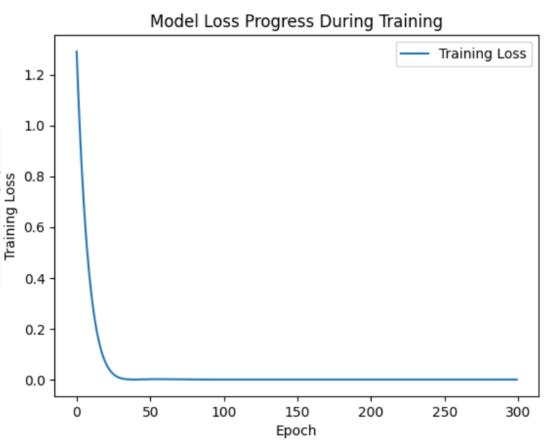

- Mean Square Error (MSE) is very similar to the Mean Absolute Error (MAE) but instead of using absolute values, squares of the difference between the model predictions and the training dataset (true values) is being calculated.
- MSE values are generally larger compared to the MAE since the residuals are being squared.
- In case of data outliers, MSE will become much larger compared to MAE
- In MSE, error increases in a quadratic fashion while the error increases in proportional fashion in MAE
- In MSE, since the error is being squared, any predicting error is being heavily penalized
- The MSE is calculated as follows:

$$MSE = \frac{1}{n} \sum_{i=1}^{n} (y_i - \hat{y}_i)^2$$

Step9: Visualize training results.

epochs_hist.history.keys()

```
plt.plot(epochs_hist.history['loss'])
plt.title('Model Loss Progress During Training')
plt.xlabel('Epoch')
plt.ylabel('Training Loss')
plt.legend(['Training Loss'])
```

26

Step10: Show model weight

```
model.get_weights()
```

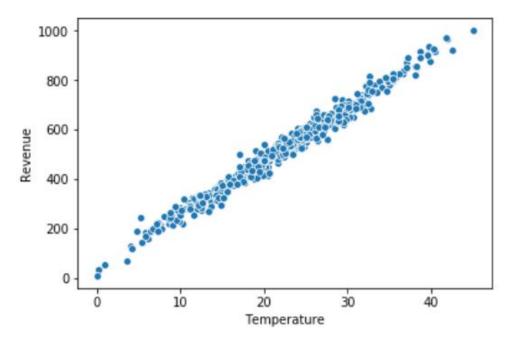

Step11: Test the model

```
f = model.predict(np.array([20]))
print(f)
```

Example2: Ice cream sales prediction

From the CSV data, create the model to predict the sales of ice cream by TF.

	Temperature	Revenue
0	24.566884	534.799028
1	26.005191	625.190122
2	27.790554	660.632289
3	20.595335	487.706960
4	11.503498	316.240194
5	14.352514	367.940744
6	13.707780	308.894518
7	30.833985	696.716640
8	0.976870	55.390338

Multi-Input Neuron Model

- Bias allows to shift the activation function curve up or down.
- Number of adjustable parameters = 4 (3 weights and 1 bias).

Activation Function

for non-linear problems

An activation function in a neural network is a mathematical function that determines whether a neuron should be activated or not based on the weighted sum of its inputs. It introduces nonlinearity, allowing the network to learn and model complex patterns beyond simple linear relationships.

Activation function	Equation	Example	1D Graph
Linear default; no activation function	$\phi(z)=z$	Adaline, linear regression	
Logistic (sigmoid)	$\phi(z) = \frac{1}{1 + e^{-z}}$	Logistic regression, Multi-layer NN	,
Hyperbolic tangent (Tanh)	$\phi(z) = \frac{e^z - e^{-z}}{e^z + e^{-z}}$	Multi-layer Neural Networks	
Rectifier, ReLU (Rectified Linear Unit)	$\phi(z) = \max(0, z)$	Multi-layer Neural Networks

output layer

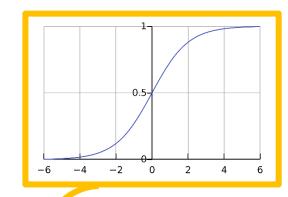

SIGMOID Function Logistic Regression

- Takes a number and sets it between 0 and 1
- Converts large negative numbers to 0 and large positive

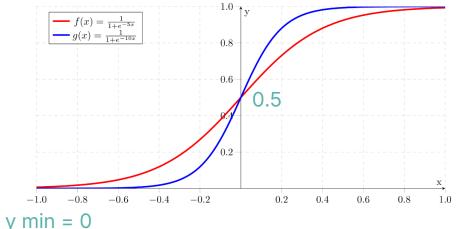

numbers to 1.

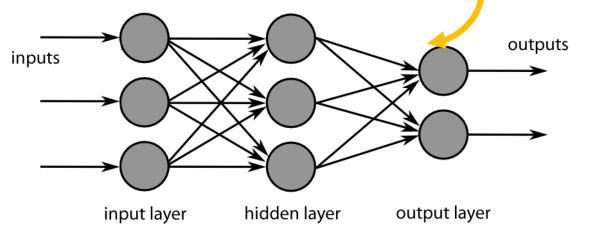

Generally used in output layer.

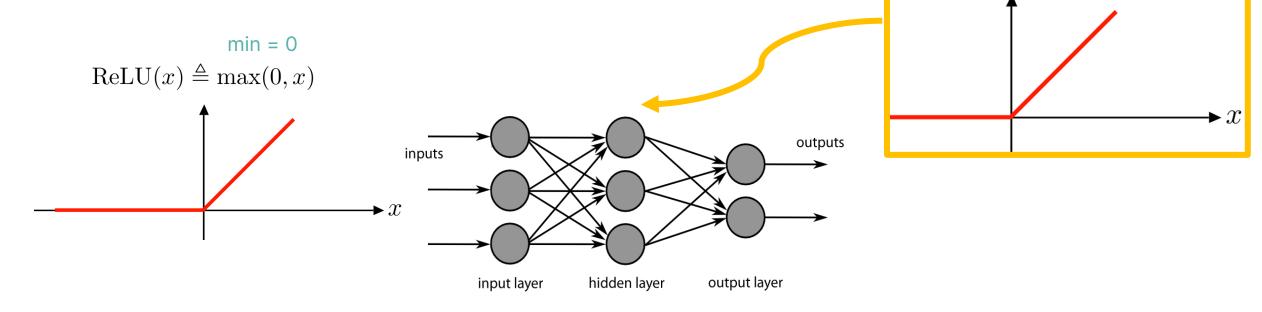

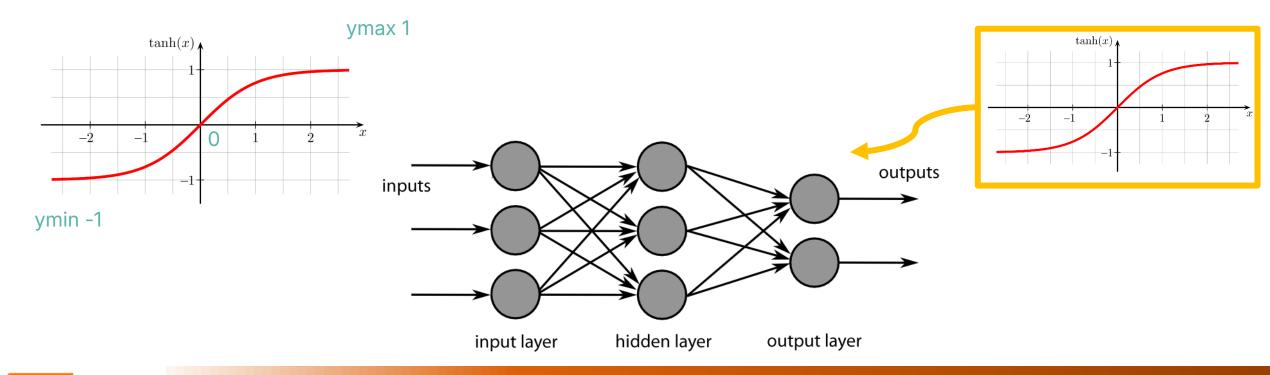

RELU (RECTIFIED LINEAR UNITS) ACTIVATION FUNCTION

- o if input x < 0, output is 0 and if x > 0 the output is x.
- o RELU does not saturate so it avoids vanishing gradient problem.
- o It uses simple thresholding so it is computationally efficient.
- Generally used in hidden layers.

HYPERBOLIC TANGENT ACTIVATION FUNCTION

- "Tanh" is similar to sigmoid, converts number between -1 and 1.
- Unlike sigmoid, tanh outputs are zero-centered (range: -1 and 1).
- Tanh suffers from vanishing gradient problem so it kills gradients when saturated.
- o In practice, tanh is preferable over sigmoid.

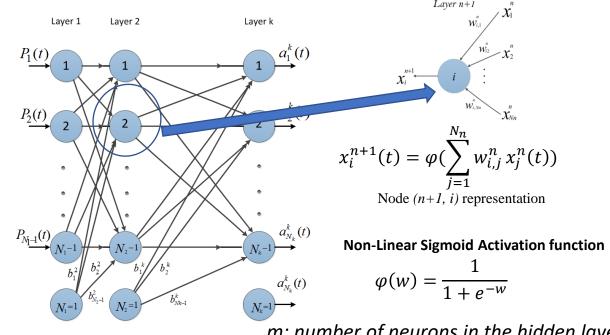

ARTIFICIAL NEURAL NETWORK REGRESSION

The more hidden layers, the more "deep" the network will get.

$$P = \begin{bmatrix} P_1 \\ P_2 \\ \vdots \\ P_{N_1} \end{bmatrix}$$

$$\begin{bmatrix} W_{11} & W_{12} & \cdots & W_{1,N_1} \\ W_{21} & W_{22} & \cdots & W_{2,N_1} \\ \vdots & \ddots & \vdots \\ W_{m-1,1} & W_{m-1,2} & \cdots & W_{m-1,N_1} \\ W_{m,1} & W_{m,2} & \cdots & W_{m,N_1} \end{bmatrix}$$

m: number of neurons in the hidden layer

 N_1 : number of inputs

ARTIFICIAL NEURAL NETWORK REGRESSION

The more hidden layers, the more "deep" the network will get.

$$P = \begin{bmatrix} P_1 \\ P_2 \\ \vdots \\ P_{N_1} \end{bmatrix}$$

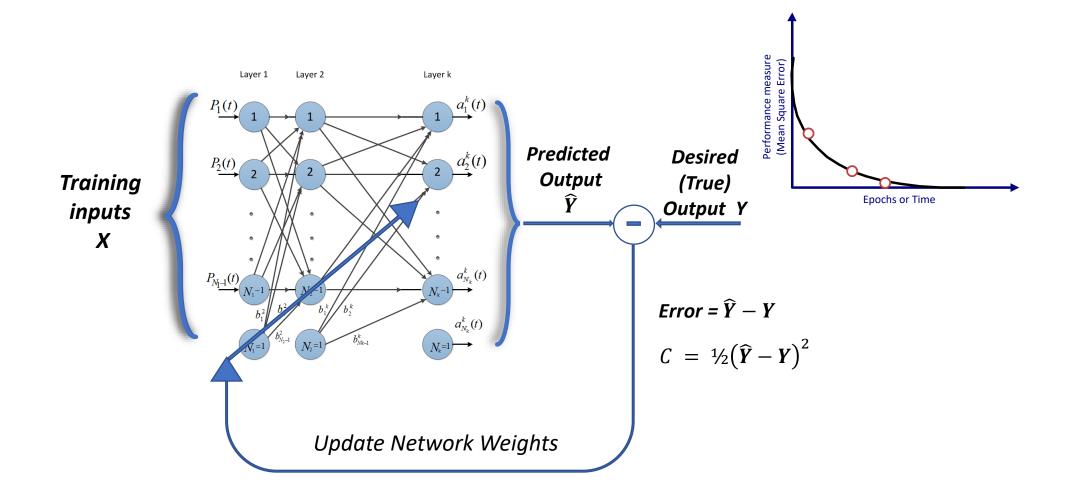

$$\begin{bmatrix} W_{11} & W_{12} & \cdots & W_{1,N_1} \\ W_{21} & W_{22} & \cdots & W_{2,N_1} \\ \vdots & \ddots & \vdots \\ W_{m-1,1} & W_{m-1,2} & \cdots & W_{m-1,N_1} \\ W_{m,1} & W_{m,2} & \cdots & W_{m,N_1} \end{bmatrix}$$

m: number of neurons in the hidden layer

 N_1 : number of inputs

ARTIFICIAL NEURAL NETWORK REGRESSION

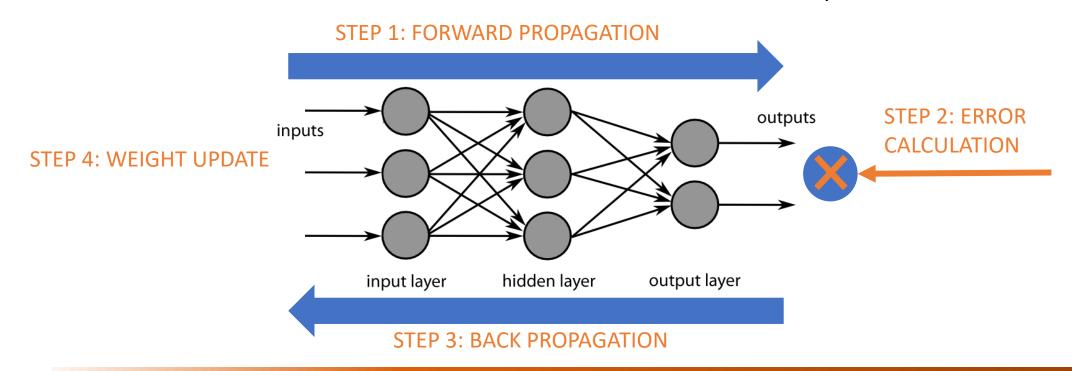

BACK PROPAGATION

- Backpropagation is a method used to train ANNs by calculating gradient needed to update network weights.
- It is commonly used by the gradient descent optimization algorithm to adjust the weight of neurons by calculating the gradient of the loss function.

BACK PROPAGATION

- Backpropagation Phase 1: propagation
 - Propagation forward through the network to generate the output value(s)
 - Calculation of the cost (error term)
 - Propagation of output activations back through network using training pattern target in order to generate the deltas (difference between targeted and actual output values)

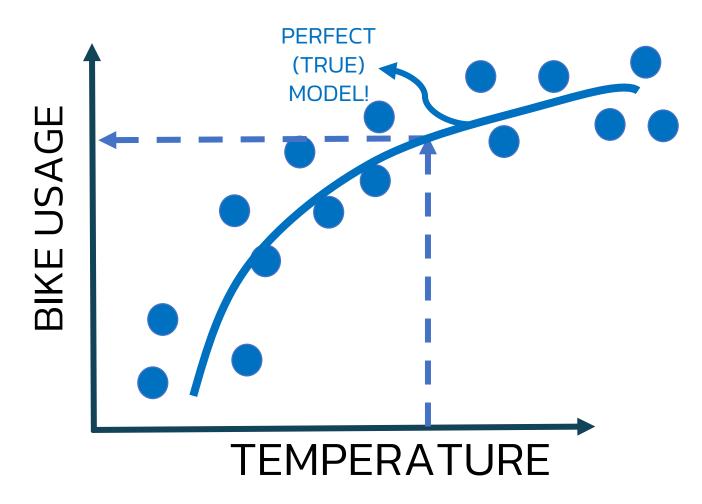

BACK PROPAGATION

- Phase 2: weight update
 - o Calculate weight gradient.
 - A ratio (percentage) of the weight's gradient is subtracted from the weight.
 - o This ratio influences the speed and quality of learning and called learning rate. The greater the ratio, the faster neuron train, but lower ratio, more accurate the training is.

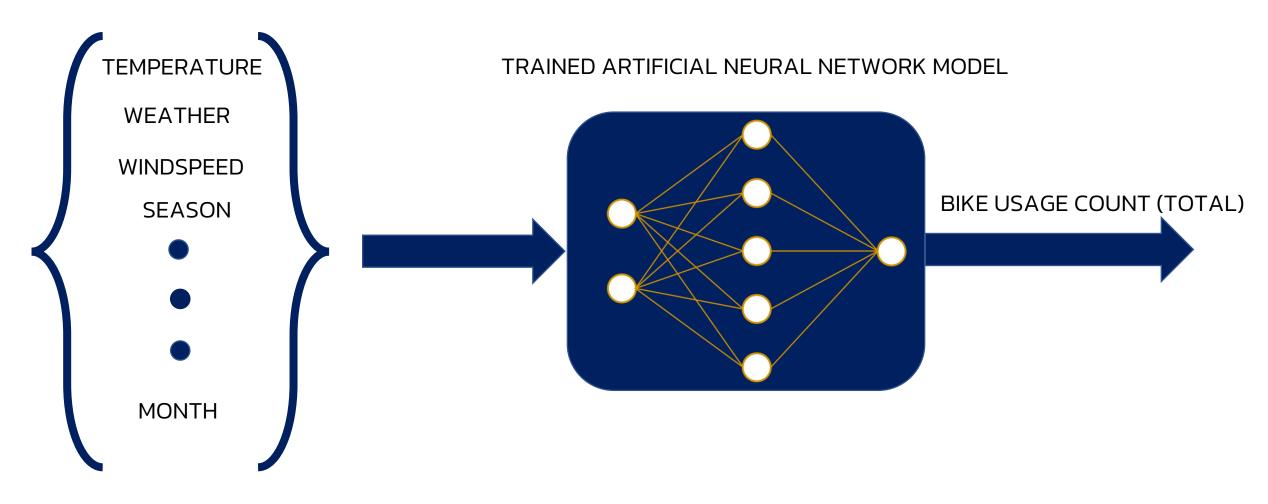

Example3: Bike Sharing Daily

- Read data from provided csv and train the model to predict the bike sharing daily.
- As temperature experience increase, the bike rental usage tend to increase as well.
- As temperature goes beyond a certain limit, usage tend to plateau and it does not increase anymore

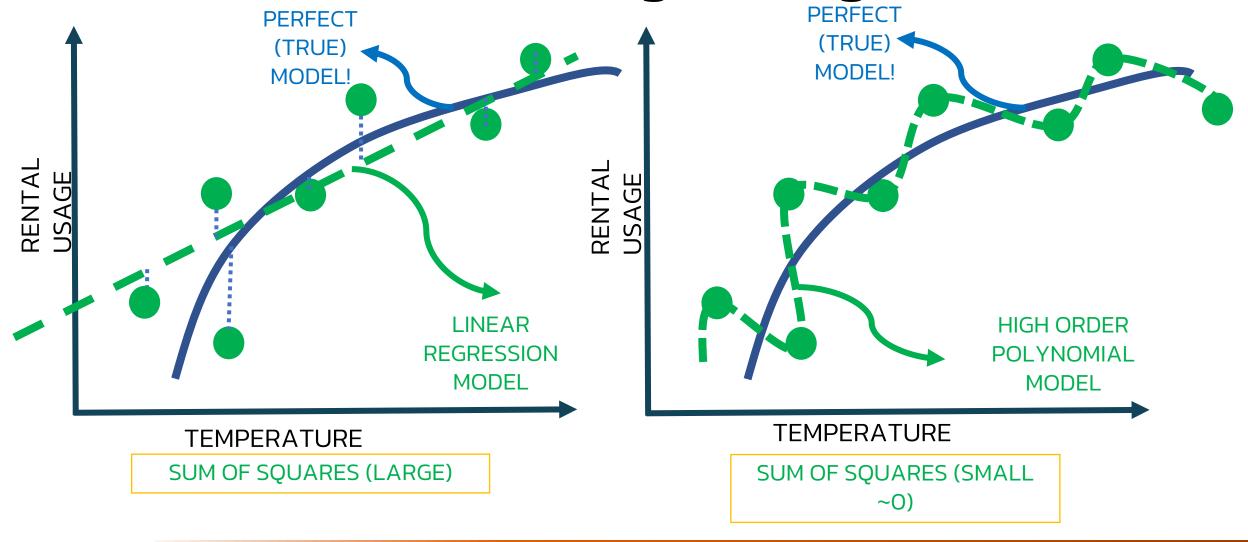

Example3: Bike Sharing Daily

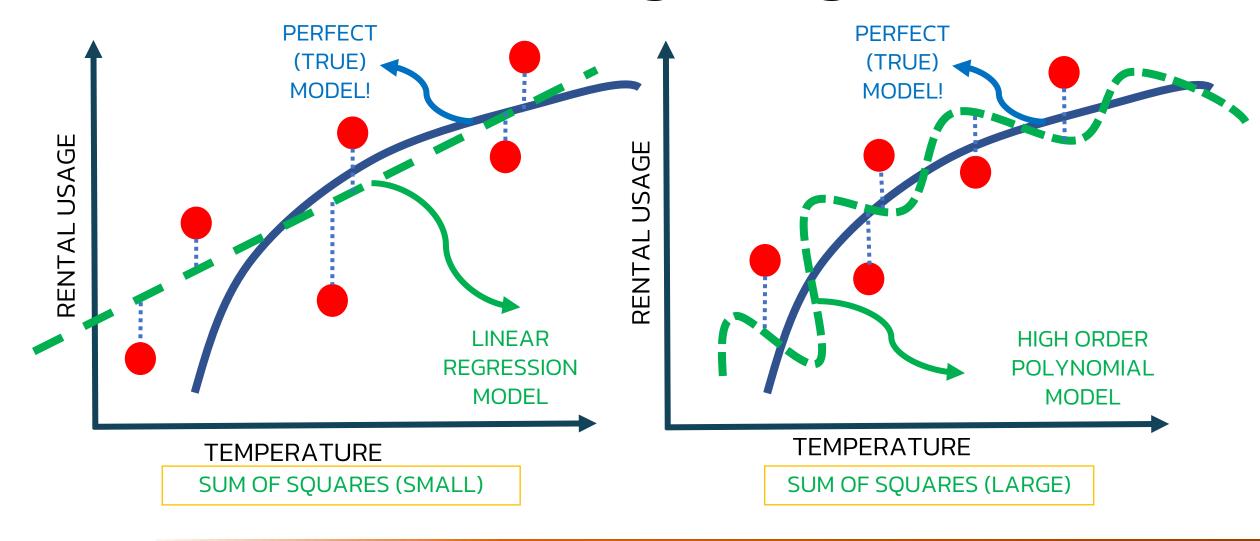

Bias and Variance during training

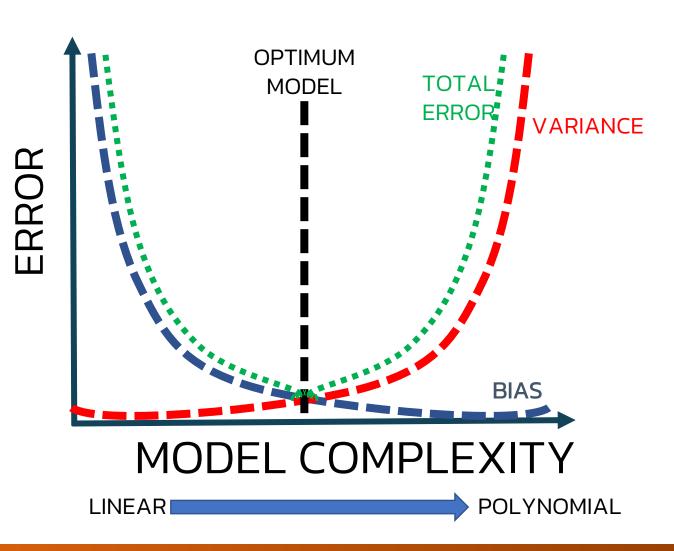

Bias and Variance during testing

Complexity vs. Error

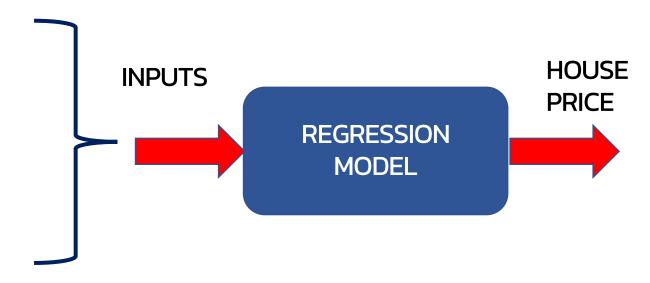

- Regularization works by reducing the variance at the cost of adding some bias to the model.
- A trade-off between variance and bias occurs

Example4: House prices prediction

- Read data from provided csv file and create the model to predict the house prices using TF.
- Dataset includes house sale prices for King County in Washington, USA.
- Homes that are sold in the time period: May, 2014 and May, 2015.
- Data Source: https://www.kaggle.com/harlfoxem/housesalesprediction
- Model inputs:
 - ida: notation for a house
 - date: Date house was sold
 - bedrooms: Number of Bedrooms
 - o bathrooms: Number of bathrooms
 - sqft_living: home square footage
 - sqft_lot: square footage of the lot
 - o floors: Total floors (levels) in house
 - waterfront: waterfront property

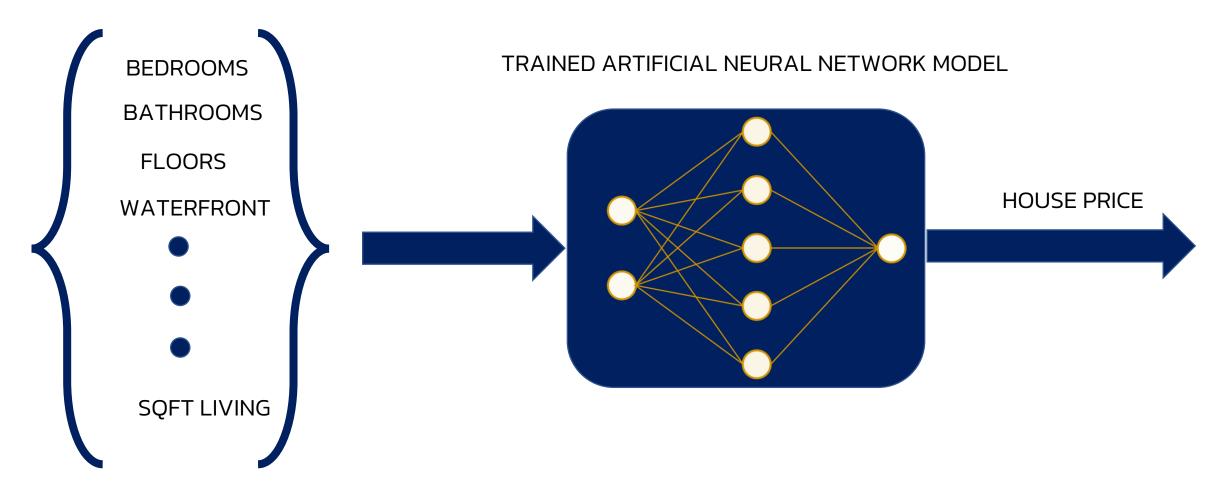

Example4: House prices prediction

- Model inputs:
 - condition: How good the condition is (Overall)
 - grade: overall grade given to housing unit, based on King County grading system
 - sqft_abovesquare: footage of house apart from basement
 - sqft_basement: square footage of the basement
 - yr_built: Built Year
 - yr_renovated: Year when house was renovated
 - zipcode: zip
 - lat: Latitude coordinate
 - long: Longitude coordinate
 - sqft_living15: Living room area in 2015
 - sqft_lot15: lotSize area in 2015(implies-- some renovations)
- The model should predict:
 - House Price

Example4: House prices prediction

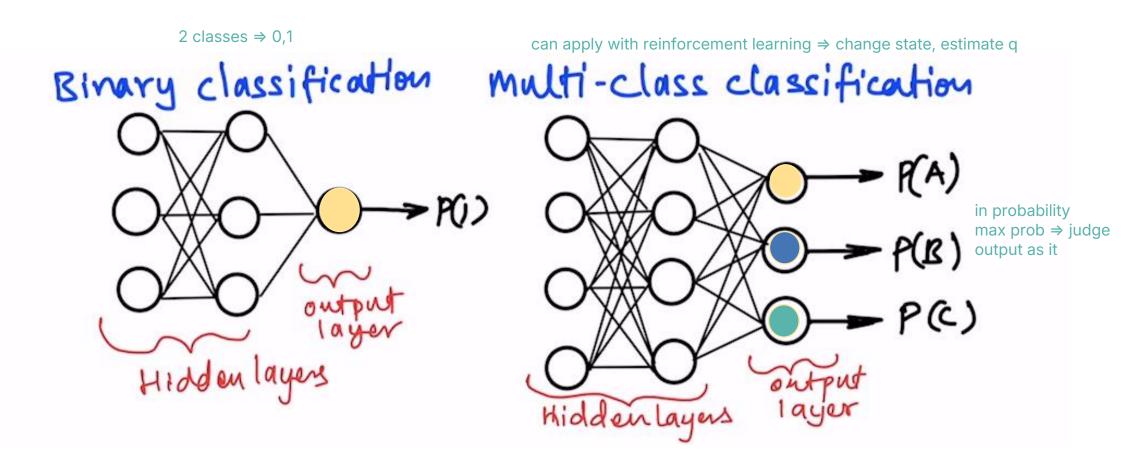

Practice

 From provided dataset of material properties and quality rating in manufacturing process, create the model to predict the quality rating using the ANNs.

- ⇒ binary cross entropy
- ⇒ catagorical cross entropy

ARTIFICIAL NEURAL NETWORK CLASSIFICATION

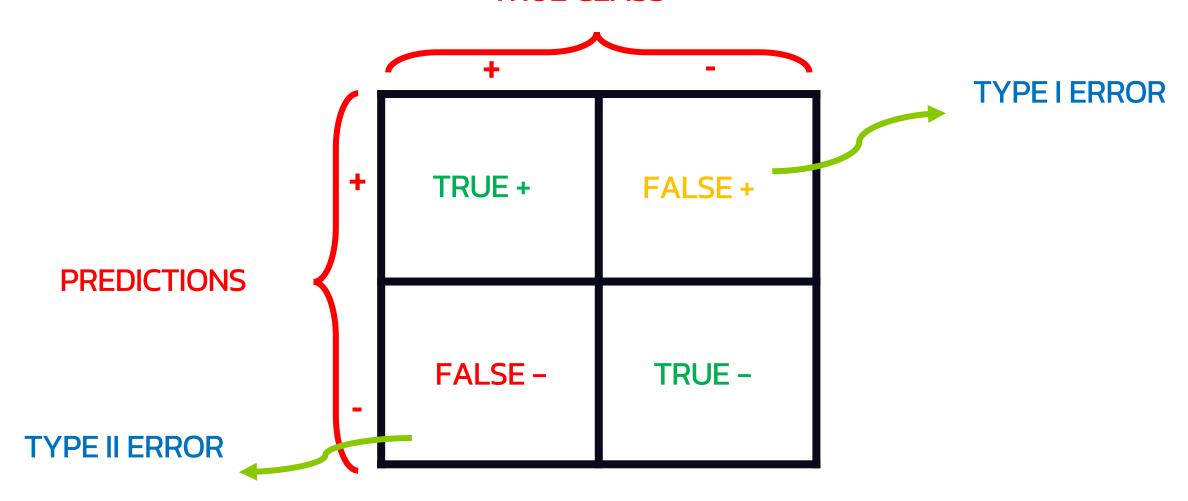

https://thinkingneuron.com/how-to-use-artificial-neural-networks-for-classification-in-python/

Confusion Matrix

TRUE CLASS

Confusion Matrix

A confusion matrix is used to describe the performance of a classification model:

- True positives (TP): cases when classifier predicted TRUE (they have the disease), and correct class was TRUE (patient has disease).
- True negatives (TN): cases when model predicted FALSE (no disease), and correct class was FALSE (patient do not have disease).
- False positives (FP) (Type I error): classifier predicted TRUE, but correct class was FALSE (patient did not have disease).
- False negatives (FN) (Type II error): classifier predicted FALSE (patient do not have disease),
 but they actually do have the disease

Confusion Matrix

- Classification Accuracy = (TP+TN) / (TP + TN + FP + FN)
- Misclassification rate (Error Rate) = (FP + FN) / (TP + TN + FP + FN)
- Precision = TP/Total TRUE Predictions = TP/ (TP+FP) (When model predicted TRUE class, how often was it right?)
- Recall = TP/ Actual TRUE = TP/ (TP+FN) (when the class was actually TRUE, how often did the classifier get it right?)

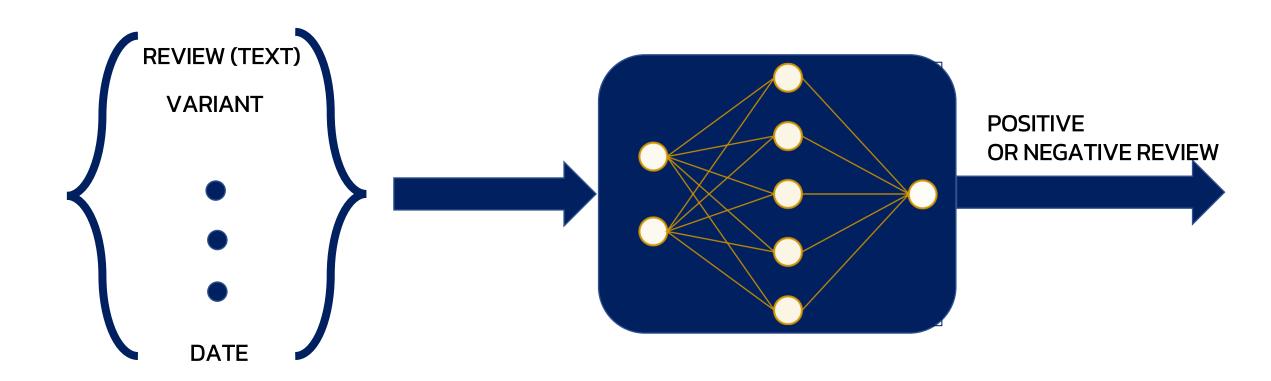

Example5: Text Classification

- Read data from provided csv file and create the model to classify type of customer reviews using TF.
- Dataset consists of 3000 Amazon customer reviews, star ratings, date of review, variant and feedback of various amazon Alexa products like Alexa Echo, Echo dots.
- The objective is to discover insights into consumer reviews and perform sentiment analysis on the data.
- Dataset: www.kaggle.com/sid321axn/amazon-alexa-reviews

Example5: Text Classification

TOKENIZATION (COUNT VECTORIZER)

Tokenization is a fundamental process in Natural Language Processing (NLP) that involves breaking down a stream of text into smaller units called tokens. These tokens can range from individual characters to full words or phrases, depending on the level of granularity required. By converting text into these manageable chunks, machines can more effectively analyze and understand human language.

This is the first document.

This document is the second document.

And this is the third one.

Is this the first document?

[[011100101] [020101101] [100110111] [011100101]]

count how many words appeared

	'and'	'document'	'first'	'is'	'one'	'second'	'the'	'third'	'this'
Training Sample #1	0	1	1	1	0	0	1	0	1
Training Sample #2	0	2	0	1	0	1	1	0	1
Training Sample #3	1	0	0	1	1	0	1	1	1
Training Sample #4	0	1	1	1	0	0	1	0	1

TOKENIZATION (COUNT VECTORIZER)

Count Vectorization

Get Key

print(vectorizer.get_feature_names())

Get Array

print(X.toarray())

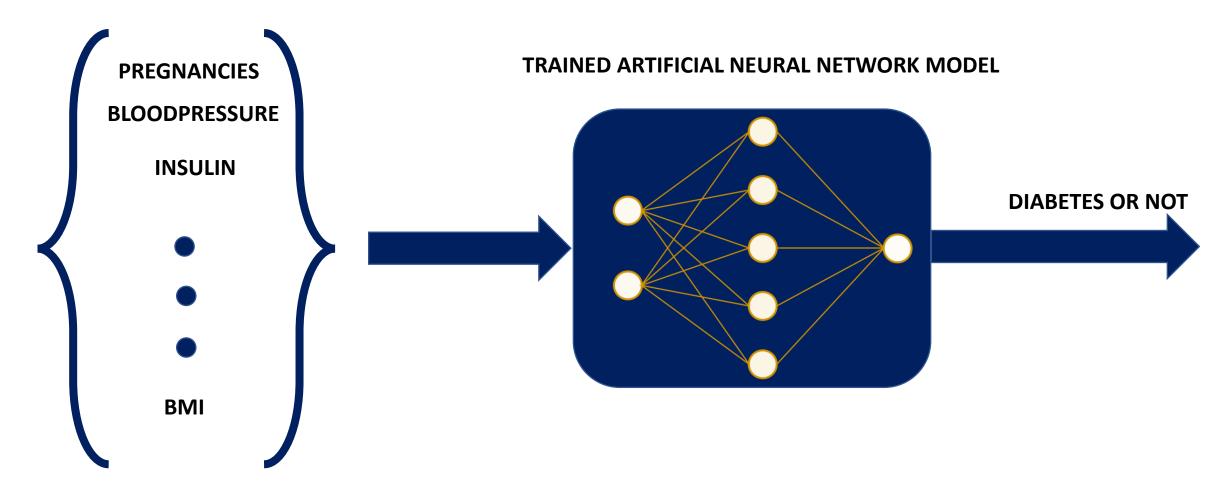

Example6: Diabetes Classification

- This dataset is used to predict whether or not a patient has diabetes, based on given features/diagnostic measurements.
- Only female patients are considered with at least 21 years old of Pima Indian heritage.
- INPUTS:
 - o Pregnancies: Number of times pregnant
 - GlucosePlasma: glucose concentration 2 hours in an oral glucose tolerance test
 - BloodPressure: Diastolic blood pressure (mm Hg)
 - Skin: ThicknessTriceps skin fold thickness (mm)
 - o Insulin: 2-Hour serum insulin (mu U/ml)
 - BMI: Body mass index (weight in kg/(height in m)^2)
 - o DiabetesPedigreeFunction: Diabetes pedigree function
 - Age: Age (years)

Example6: Diabetes Classification

Practice

• From provided Wafer manufacturing data, create ANNs model to detect anomaly in the process by TF.

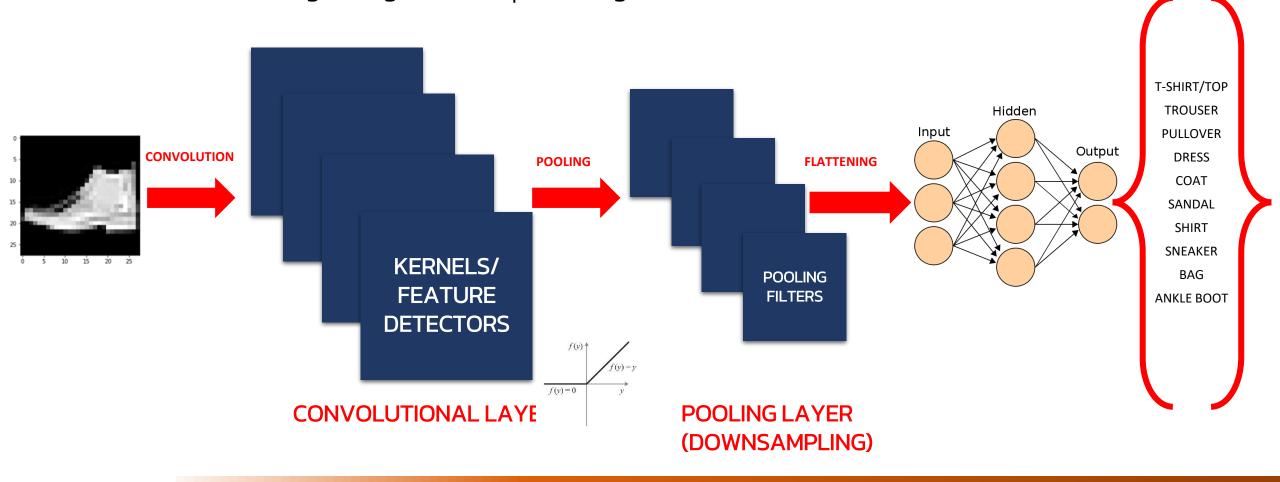

Mecha tronics

Day10 Convolutional Neural Networks (CNNs)

Overview

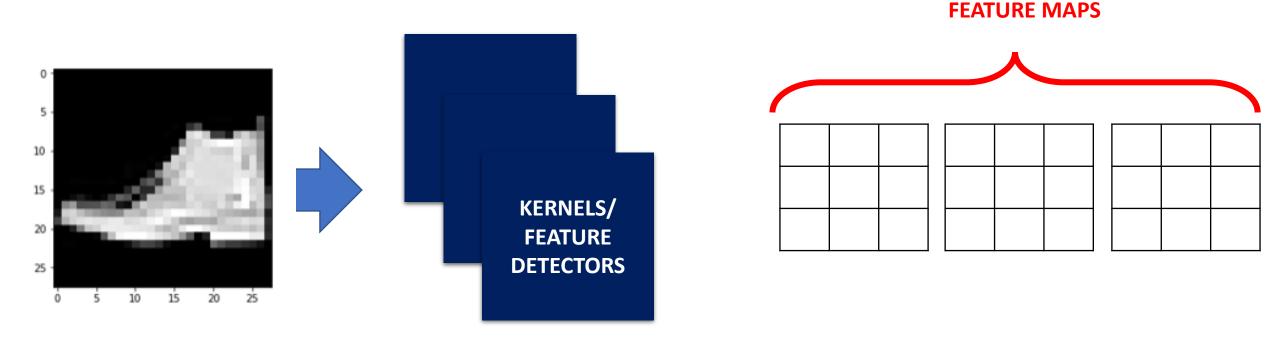

A Convolutional Neural Network (CNN) is a type of deep learning algorithm that is particularly well-suited for image recognition and processing tasks

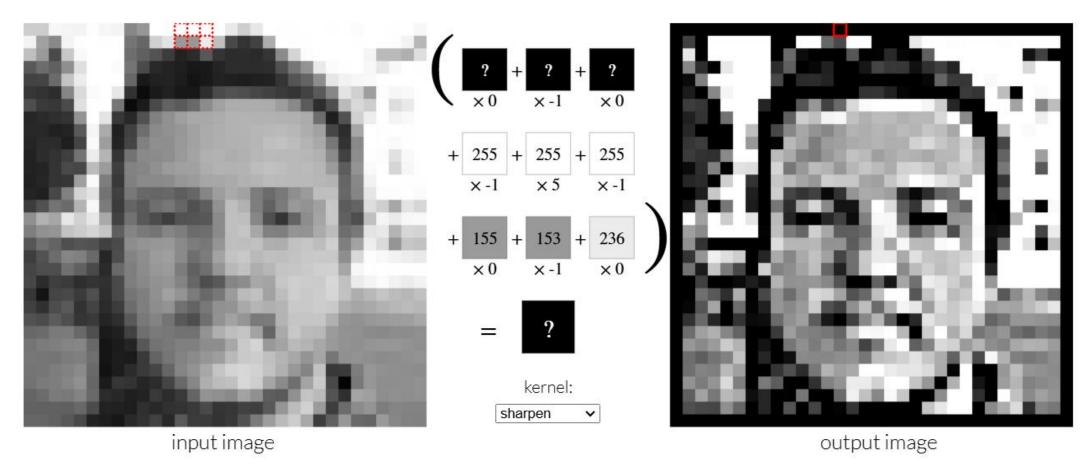

Feature Detectors

- Convolutions use a kernel matrix to scan a given image and apply a filter to obtain a certain effect.
- An image Kernel is a matrix used to apply effects such as blurring and sharpening.
- Kernels are used in machine learning for feature extraction to select most important pixels of an image.
- Convolution preserves the spatial relationship between pixels.

Feature Detectors

https://setosa.io/ev/image-kernels/

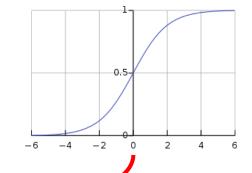

ReLU in CNNs

• ReLU Layers are used to add non-linearity in the feature map.

It also enhances the sparsity or how scattered the feature map is. T-SHIRT/TOP TROUSER Hidden Input **PULLOVER** Output CONVOLUTION **DRESS FLATTENING POOLING** COAT **SANDAL SHIRT SNEAKER KERNELS/** BAG **POOLING FEATURE FILTERS** ANKLE BOOT $f(y) \uparrow$ **DETECTORS** f(y) = yf(y) = 0**CONVOLUTIONAL LAYER POOLING LAYER** (DOWNSAMPLING)

ReLU in CNNs

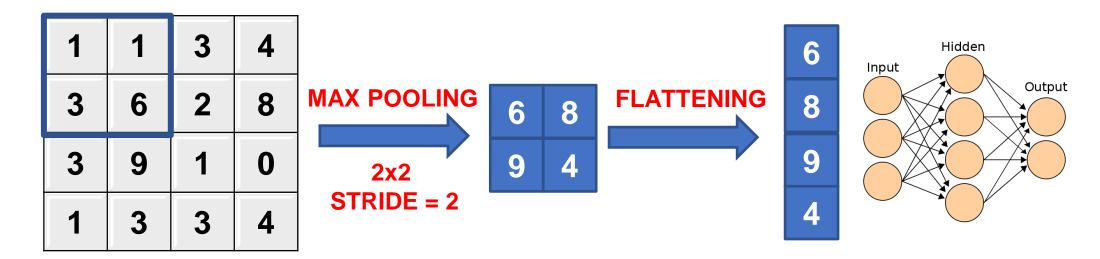

- RELU Layers are used to add non-linearity in the feature map.
- It also enhances the sparsity or how scattered the feature map is.
- The gradient of the RELU does not vanish as we increase x compared to the sigmoid function

7	10	-5	2	1		7	10	0	2	1
1	0	2	3	-6	f(y)	1	0	2	3	0
1	17	-5	0	0	f(y) = y	1	17	0	0	0
0	1	1	1	0	$f(y) = 0 \qquad y$	0	1	1	1	0
0	0	-8	12	1		0	0	0	12	1

Pooling (Down Sampling)

- Pooling or down sampling layers are placed after convolutional layers to reduce feature map dimensionality.
- This improves the computational efficiency while preserving the features.
- Pooling helps the model to generalize by avoiding overfitting.
- If one of the pixel is shifted, the pooled feature map will still be the same.
- Max pooling works by retaining the maximum feature response within a given sample size in a feature map.

CNC Explainer

• https://adamharley.com/nn_vis/cnn/3d.html

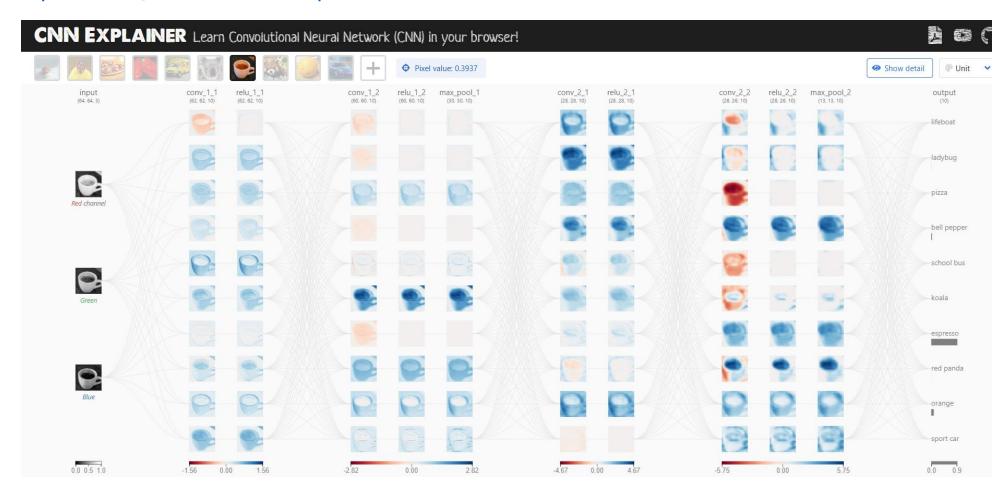

standard input size: 224 x 224 pixel

CNC Explainer

• https://poloclub.github.io/cnn-explainer/

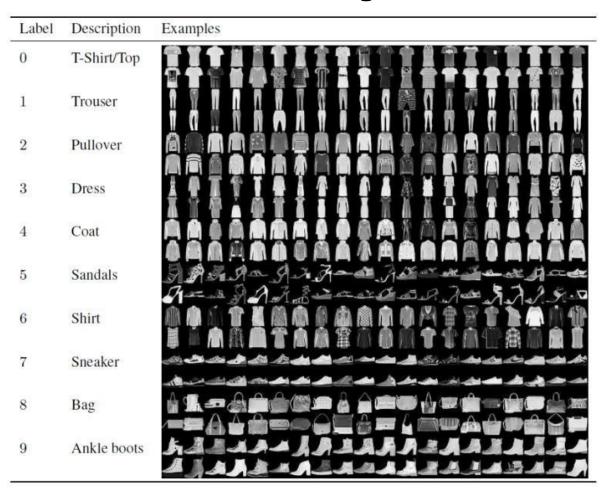

or could be reduce for edge device (Tensorflow lite Converter)

• Create the CNNs model for fashion MNIST datasets classification using TF.

Step1: Download and split dataset.

```
fashion_mnist = tf.keras.datasets.fashion_mnist

(train_images, train_labels), (test_images, test_labels) = fashion_mnist.load_data()
```

Step2: Create model.

```
model = tf.keras.models.Sequential()
model.add(tf.keras.layers.Conv2D(32, (3,3), activation = 'relu', input_shape = (28,28,1)))
model.add(tf.keras.layers.MaxPooling2D(2,2))
model.add(tf.keras.layers.Conv2D(64, (3,3), activation = 'relu'))
model.add(tf.keras.layers.Conv2D(64, (3, 3), activation='relu'))
model.add(tf.keras.layers.Conv2D(64, (3, 3), activation='relu'))
model.add(tf.keras.layers.Flatten())
model.add(tf.keras.layers.Platten())
model.add(tf.keras.layers.Dense(64, activation = 'relu'))
model.add(tf.keras.layers.Dense(10, activation = 'softmax'))
```

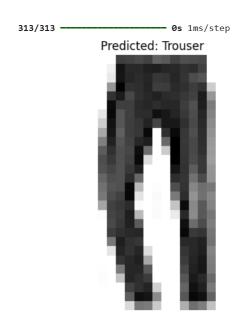

Step3: Train model.

Step4: Evaluate model.

```
evaluation = model.evaluate(test_images, test_labels)
print('Test Accuracy : {:.3f}'.format(evaluation[1]))
```

Step5: Test model.

 From provided dataset, create the model to classify the image between steak and pizza using TF.

Step1: Upload provided zip file to the google drive.

Step2: Extract file.

```
import zipfile

zip_ref = zipfile.ZipFile("/content/drive/MyDrive/
zip_ref.extractall()
zip_ref.close()
/EX8/pizza_steak.zip", "r")
```

Step3: Generate dataset from image.

Step4: Create model.

```
model = tf.keras.models.Sequential()
model.add(tf.keras.layers.Conv2D(10, 3,activation="relu", input_shape=(224, 224, 3)))
model.add(tf.keras.layers.Conv2D(10, 3, activation = "relu"))
model.add(tf.keras.layers.MaxPool2D())
model.add(tf.keras.layers.Conv2D(10, 3, activation = "relu"))
model.add(tf.keras.layers.Conv2D(10, 3, activation = "relu"))
model.add(tf.keras.layers.MaxPool2D())

model.add(tf.keras.layers.Flatten())
model.add(tf.keras.layers.Dense(1, activation="sigmoid"))
```

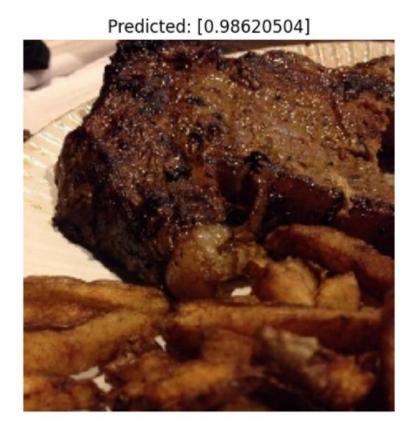

Step5: Train model.

Step6: Test the result.

```
from tensorflow.keras.preprocessing import image
img_path = "/content/pizza_steak/test/steak/1012080.jpg"
img = image.load_img(img_path, target_size=(224, 224))
img array = image.img to array(img)
img array = np.expand dims(img array, axis=0)
img array /= 255.0
prediction = model.predict(img array).flatten()
class names = ['pizza', 'steak']
plt.imshow(img)
plt.title(f"Predicted: { [prediction[0]] }")
plt.axis("off")
plt.show()
```

Practice

• From pill QC datasets, create CNNs model to classify OK pill and NG pill by TF. [chip, dirt, normal]

INSTITUTE OF ENGINEERING
